1 Background

The programs below simulate an 11-stage shift register with feedback to produce a maximal-length shift register sequence. Such a sequence is a pseudo-random sequence. Its auto-correlation is 2047 for offsets of 0 and multiples of 2047, and -1 for all other offsets. The spectrum of the output of the device is a comb spectrum.

With an oscillator input of 16.384 MHz, the internal clock runs at 16.384/4 or 4.096 MHz. The cycle time for the shift register loop is 8 instructions, so the virtual clock for the shift register is 512 kHz. With a cycle length of 2047 shifts, the pseudo-random sequence repeats at a rate of 250.1221 Hz, which is the spacing of the components of the comb spectrum.

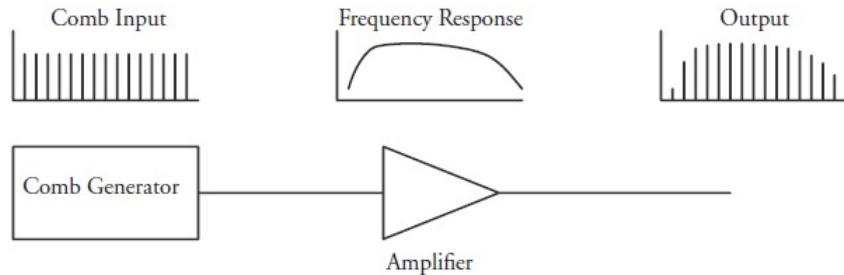

Figure 1: Illustration of expected responses for comb calibration.

The microprocessor used to execute this code is the PIC12F629. Its pin configuration can be seen here:

3 Appendix

3.1 Assembly Notes

This code was written in MPLABX ver. 5.35 using the MPASM compiler. The configuration word and pre-processor instructions are defined specifically for the PIC12F629 microcontroller. The number of loop instructions correspond to an 11-stage linear feedback shift register, designed to produce spectral combs spaced 244.26 Hz apart.

```

3.2 C Notes

This code will produce the same result as the assembly code above, but the XC8 compiler is not fast enough to generate in-phase outputs on all required GPIO pins. If one tethers two identical output pins, they would see a voltage division in the output due to the delay incurred by down-compiling the C code. Use this code if you have a faster micro-controller or a more reliable C compiler. This program was last executed on MPLAB ver. 6.10 using the supported XC8 compiler.

3.2.1 Source Code

```

1 #include <xc.h>
2 #include <stdio.h>
3 #include <stdint.h>
4 #include <stdlib.h>
5
6 // Configuration bits
7 #pragma config FOSC = EC      // GP4 operates as I/O, CLKIN on
                                // GP5
8 #pragma config WDIE = OFF     // Watchdog timer disabled
9 #pragma config PWRTE = OFF    // Power-up timer disabled

```

```

10 #pragma config MCLRE = OFF      // MCLR pin function is digital I/
11                                     O
12 #pragma config BOREN = OFF      // Brown-out reset disabled
13 #pragma config CP = OFF        // Code protection disabled
14 #pragma config CPD = OFF       // Data code protection disabled
15
16 void main()
17 {
18     TRISIO &= 0xE8;    // set TRISIO (0, 1, 2, 4) as output
19     GPIO = 0;          // set all declared GPIO pins as outputs
20
21     const uint16_t start = 0x002; // algorithm seed (0b 0000
22                                     0000 0010)
23     const uint16_t mask = 0x07FF; // constant mask for
24     autocorrelation range (0d 2047)
25     uint16_t a = start;         // set autocorrelation equal
26                                     to starting seed
27
28     while (1) {
29
30         unsigned int newbit = ((a >> 10) ^ (a >> 1)) & 1; // generate new bit using LSFR logic with two taps at 2^10, 2^1
31                                     bits
32         a = ((a << 1) | newbit) & mask; // apply the new bit and
33                                     mask the value to the autocorrelation
34                                     range
35
36         // ternary operation to determine if sequence is
37         // complete. If so, set all GPIO outputs equal to seed
38         GPIO = a == start ? (start & 0xFF) : (a & 0xFF << 4) |
39         (~a & 0x03); // set GPIO pins based on the autocorrelation
40         value
41     }
42 }
```
